## Conclusions

- Remission spectroscopy (O<sub>2</sub>C) represents a simple and reliable method for hepatic sinusoidal SO<sub>2</sub> determination.
- Significant reduction in hepatic SO<sub>2</sub> during early stages of systemic inflammation
  - in parallel an increasing NAD(P)H autofluorescence (=inadequate oxygen supply)
  - in parallel an increasing marker of liver cell injury

# Comparison O<sub>2</sub>C(oxygen to see) measurements and NAD(P)H fluorescence on liver tissue (Dr. Wunder, Anaesthesia, Würzburg)

A remission spectroscopy system for in vivo monitoring of murine hepatic sinusoidal hemoglobin oxygen saturation and its association with NAD(P)H autofluorescence and markers of hepatocyte cellular injury in a murine model in early systemic inflammation.

- sham
- 1 hour bilateral hindlimb ischemia and 3 hours of reperfusion
- 6 hour bilateral hindlimb ischemia and 6 hours of reperfusion
